# Gradual change in these factors can erode landscape resilience

# The *ForWarn* system

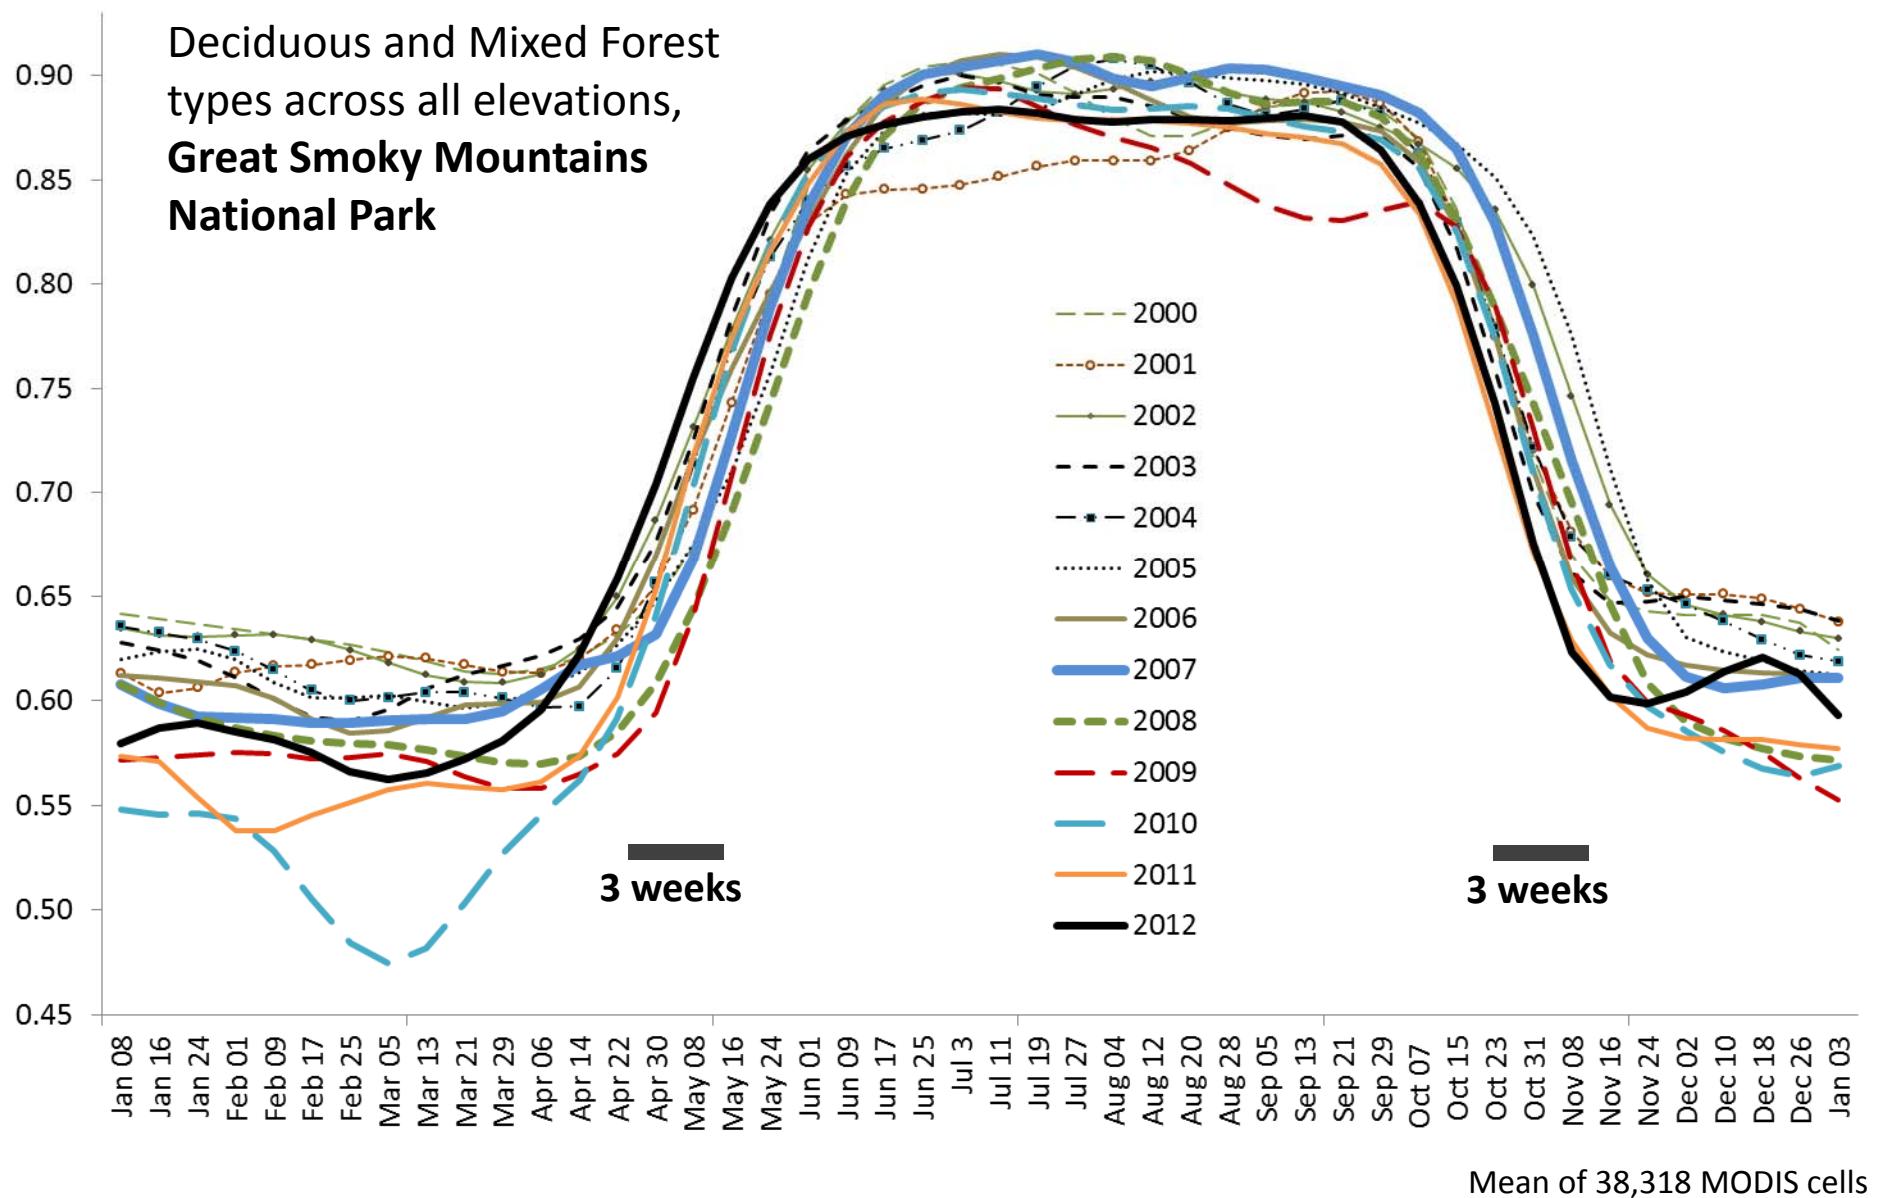

- Normalized Difference Vegetation Index (NDVI) from daily eMODIS and MODIS
- 232 meter resolution
- 46 periods per year (8-day intervals)
- Max value of 24-day moving window
- 2000 to present historical database
- Includes NDVI time series and change maps
- Online: <http://forwarn.forestthreats.org>

## Baselines

- 1 year Early Detect
- 1 year value
- 3 year maximum
- All year maximum
- All year mean
- All year type mean

# Summary

- High-frequency monitoring of canopy greenness provides a broad suite of measures for monitoring both sudden and gradual forest change.
- For local areas, disturbance and recovery can be monitored directly: this relates to local resilience.
- More broadly, net change relates to landscape resilience which can be mapped for contextualizing threats, identifying specific forests at risk and for prioritizing active management solutions.
